Vaccination in Adults
Make Sure Your Nurses’ Skills are Sharp

Did you know that approximately 42,000 adults in the U.S. alone die from vaccine-preventable diseases every year? While some diseases have been eradicated in certain parts of the world, they are still prevalent in some areas today. Vaccination plays a key role in reducing vaccine-preventable diseases. Now you can participate in that effort while you’ve been asked to. In addition to preventing disease, it reduces the overall cost of medical care and improves workforce productivity by reducing the number of days lost from school due to vaccine-preventable illnesses.

Administering vaccinations is a common part of many nurse’s daily work. But nurses will only be as effective as their own knowledge and competency. Here are some tips to help you do your job in the best way possible.

**POST-PROCEDURE STEPS**
- Review the facility/unit protocol for administering immunizations to adults, if one is available
- Review the treating clinician’s order for immunization
- Note the type and dose of vaccine ordered and route of administration
- Review the patient’s medical history/medical record
- Follow standard pre-procedure steps
- Verify the “rights” of medication administration. See medication administration “rights.”
- Assist the patient into a comfortable position that allows easy access to the area of the body where the immunization will be administered
- Use an alcohol swab or facility-approved antiseptic to clean the injection site using a circular motion
- Allow the site to air-dry
- Uncap the syringe
- Use techniques to promote effective vaccine delivery in target tissue, minimize injection site pain, and reduce risk for local reactions
- Use I.M. administration for most vaccinations
- Use Z-track injection if appropriate
- Administer vaccinations in a larger muscle
- Select the appropriate needle length for the vaccination administration
- Stretch or spread the skin flat, with your nondominant hand, between the thumb and index finger to create a firm surface and to isolate the muscle
- Use your dominant hand to hold the syringe between the thumb and forefinger as if holding a dart
- Position the needle at a 90° angle to the surface of the injection site and pierce the patient’s skin with the needle using a smooth, rapid motion
- Inject the vaccine
- Gently withdraw the needle using the same track as for injection, and release the skin to its normal position
- Cover the injection site with a bandage
- Do not massage the skin or muscle tissue at the site of the injection because doing so can irritate the muscle tissue and/or force some of the medication into the subcutaneous tissue
